

## OpenOCD CLI user guide

#### About this document

#### **Scope and purpose**

This user guide provides technical information for the ModusToolbox™ version of the OpenOCD command line tool, including how to use it in stand-alone mode. OpenOCD is an Open Source programmer/debugger software that is installed as part of either the CYPRESS™ Programmer or ModusToolbox™ software.

#### Intended audience

This document is intended for anyone who wants to use the OpenOCD CLI as a stand-alone tool.

#### **Document conventions**

Convention Explanation		
<b>Bold</b> Emphasizes heading levels, column headings, menus and sub-menus		
Italics	Denotes file names and paths.	
Courier New	Denotes APIs, functions, interrupt handlers, events, data types, error handlers, file/folder names, directories, command line inputs, code snippets	
File > New Indicates that a cascading sub-menu opens when you select a menu item		

#### **Abbreviations and definitions**

The following define the abbreviations and terms used in this document:

- OpenOCD Open On-Chip Debugger. An open-source tool that allows programming internal and external flash memories of a wide range of target devices.
- CLI Command-line interface.
- Tcl Tool command language. A high-level, general-purpose, interpreted, dynamic programming language.
- MPN Marketing part number. This number is associated with each specific device and used to order a
  device or find information about a device from Infineon. For example, CY8C616FMI-BL603, CY8C616FMIBL673.
- SWD Serial wire debug interface.
- JTAG Joint Test Action Group. Specifies the use of a dedicated debug port implementing a serial communication interface for low-overhead access without requiring direct external access to the system address and data buses.
- TAP JTAG test access port.
- PSoC<sup>™</sup> A family of microcontroller integrated circuits by Infineon. These chips include a CPU core and mixed-signal arrays of configurable integrated analog and digital peripherals.
- MCU Microcontroller unit.
- AP Access port register of Arm® Cortex® CPU. Used for programming and debugging, along with the corresponding SWD address bit selections.
- DP Debug port register of Arm® Cortex® CPU. Used for programming and debugging, along with the corresponding SWD address bit selections.

#### **About this document**

Region – A logical area within the target device the programmer operates on.

#### **Reference documents**

#### Introduction

### 1 Introduction

#### 1.1 Overview

The ModusToolbox™ OpenOCD command-line interface (CLI) is based on the Open On-Chip Debugger (OpenOCD) product. OpenOCD is a powerful tool whose interface interacts with the target device via the JTAG/SWD debug ports. OpenOCD allows programming internal and external flash memories of a wide range of target devices, CFI-compatible flashes, and some CPLD/FPGA devices.

This document covers the ModusToolbox™-specific CLI extensions of OpenOCD. See the official documentation at:

http://openocd.org/documentation/

The latest released version of ModusToolbox™ OpenOCD is available from the GitHub repository:

https://github.com/Infineon/openocd/releases

## 1.2 Supported OS

- Windows 7 SP1 (x86 / x64)
- Windows 10 (x86 / x64)
- Linux Ubuntu 18.04 "Bionic Beaver", Ubuntu 20.04 "Focal Fossa"
- macOS 10.15 "Catalina", macOS 11 "Big Sur"

## 1.3 Supported devices

- AIROC™ CYW20809 Bluetooth® LE system on chip
- PSoC<sup>™</sup> 6 and PSoC<sup>™</sup> 64
- PSoC™ 4
- CYW4390x [1]

## 1.4 Supported hardware (probes)

- SEGGER J-Link
- Infineon KitProg3 on-board programmer
- Infineon MiniProg4 standalone programmer
- FTDI-based adapter on CYW954907AEVAL1F / CYW943907AEVAL1F kits

<sup>&</sup>lt;sup>1</sup> Currently, OpenOCD does not provide a "built-in" Flash driver for the CYW4390x chip. All Flash-related operations are fully implemented in the TCL scripts. The behavior of the TCL-based driver is slightly different from the built-in one. Refer to the <a href="https://creativecommons.org/linearing-nc-based-nc-base

#### Introduction

### 1.5 Installation

The ModusToolbox™ OpenOCD CLI software is installed as part of either CYPRESS™ Programmer or ModusToolbox™ software. You can also download the latest version from the GitHub repository:

https://github.com/Infineon/openocd/releases

Refer the ModusToolbox™ software installation guide for details.

Note: CYPRESS™ Programmer is not part of ModusToolbox™ software and must be installed separately.

See the  $\underline{CYPRESS^{\mathsf{TM}}Programmer}$  GUI user guide.

#### 1.6 Error codes

The OpenOCD tool returns '0' as the response code on successful completion; on a failure, it returns '1'.

#### **Getting started**

## 2 Getting started

#### 2.1 Connect the device

Connect the host computer to a probe or kit device; e.g. KitProg3 kit with the PSoC<sup>™</sup> 6 MCU target, used in the following examples. Make sure that the target MCU is attached to your probe.

## 2.2 List the connected targets

This example displays the target names available for the PSoC™ 6 MCU connected to the KitProg3 programmer. The programmer communicates with the PSoC™ 6 MCU over the SWD interface.

#### **2.2.1** Windows:

1. On a command-line window, enter the following command to change the directory to the CYPRESS™ Programmer or ModusToolbox™ software installation folder:

```
cd %installation folder%\openocd\bin
```

2. Run the following command:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "targets;
shutdown"
```

```
Open On-Chip Debugger 0.10.0+dev-2.1.0.47 (2018-12-04-04:07)
Licensed under GNU GPL v2
For bug reports, read
http://openocd.org/doc/doxygen/bugs.html
adapter speed: 1500 kHz
Warn : Transport "swd" was already selected
adapter speed: 1000 kHz
** Auto-acquire enabled, use "set ENABLE_ACQUIRE O" to disable
cortex_n reset_config sysresetred
cortex_n reset_config vectreset
adapter_nsrst_delay: 100

TargetName Type Endian TapName State

0* psoc6.cpu.cm0 cortex_m little psoc6.cpu unknown
1 psoc6.cpu.cm4 cortex_m little psoc6.cpu unknown
5 butdown command invoked
```

The command output displays the list of target names (JTAG TAPs) attached to the programming device.

#### 2.2.2 **Linux**:

- 1. On the terminal window, go to the directory where CYPRESS™ Programmer or ModusToolbox™ software is installed (for example, ~/openocd/bin).
- 2. Run the following command:

```
./openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "targets;
shutdown"
```

The command output displays the list of target names (JTAG TAPs) attached to the programming device.

#### 2.2.3 macOS:

- 1. One the terminal window, go to the directory where CYPRESS™ Programmer or ModusToolbox™ software is installed (for example, ~/openocd/bin).
- 2. Run the following command:

```
./openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "targets; shutdown"
```

The command output displays the list of target names (JTAG TAPs) attached to the programming device.

## 2.3 Program the PSoC<sup>™</sup> 6 MCU target

This example initializes the KitProg3 probe with the PSoC™ 6 MCU, programs the flash with the *firmware.hex* file, verifies the programmed data, and finally shuts down the OpenOCD programmer.

Run the following command:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "program d:/firmware.hex verify exit"
```

## 2.4 Program the PSoC™ 64 "Secure Boot" MCU target

This example initializes the KitProg3 probe with the PSoC<sup>™</sup> 64 MCU, programs the flash with the *firmware.hex* file, verifies the programmed data, and finally shuts down the OpenOCD programmer.

Run the following command:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6_secure.cfg -c
"program d:/firmware.hex verify exit"
```

Note:

The psoc6\_secure.cfg configuration file programming of the internal flash is performed via the SYS\_AP access port. OpenOCD will not affect CM0\_AP and CM4\_AP by default, so both cores will not be visible to OpenOCD. Choose the access port using the <u>TARGET\_AP</u> variable.

Programming of the external memory is done by the flash loader, so the CM4 access port must be used for QSPI memory programming. After choosing the CM4 access port, the QSPI memory bank will be exposed automatically.

Note: See <u>Supported target configurations</u> for the list of available target configurations.

#### **Getting started**

## 2.5 Program the PSoC<sup>™</sup> 4 MCU target

This example initializes the KitProg3 probe with the PSoC<sup>™</sup> 4 MCU, programs the flash with the *firmware.hex* file, verifies programmed data, and finally shuts down the OpenOCD programmer.

Execute the following command:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc4.cfg -c "program
d:/firmware.hex verify exit"
```

## 2.6 Program the device using the configuration file only

The whole configuration is stored in a single *sample.cfg* configuration file. For example, the following configuration file describes the PSoC<sup>™</sup> 6 MCU connected using the KitProg3 debug probe. This file initializes the target device, programs the flash with the *firmware.hex* file, verifies programmed data, and finally shuts down the OpenOCD programmer.

```
source [find interface/kitprog3.cfg]
transport select swd
source [find target/psoc6.cfg]
program d:/firmware.hex verify exit
```

Execute the following command:

```
openocd -s ../scripts -f path/to/sample.cfg
```

## 2.7 Program the device using the configuration file and command line

A significant part of the configuration file specifies the debug adapter, transport type, target chip, SWD frequency, reset type, etc. This part of the file reflects the hardware configuration and thus stays unchanged between sessions. In some cases, a combined method of passing the Tcl commands is more convenient.

The example *sample.cfg* file contents:

```
source [find interface/kitprog3.cfg]
transport select swd
source [find target/psoc6.cfg]
```

Execute the following command:

```
openocd -s ../scripts -f path/to/sample.cfg -c "program d:/firmware.hex verify exit"
```

## 2.8 Remote debugging of PSoC™ 6 MCU target

OpenOCD is a server application which implements the remote *gdbserver* protocol and, as such, supports remote debugging out of the box. All communication between the debugger (GDB) and OpenOCD is done via TCP connections, even when debugging a locally connected target. This example shows how to configure ModusToolbox™ software for remote debugging and launch a remote debug session of the PSoC™ 6 MCU target.

This example uses two PCs: a local PC where ModusToolbox<sup>™</sup> software will be running and a remote PC with the CY8CPROTO-062-4343W kit connected. The remote PC runs OpenOCD and acts as a server; both machines will communicate via TCP protocol.

#### On a local machine:

1. Start the ModusToolbox<sup>™</sup> software. Create and build a project for CY8CPROTO-062-4343W.

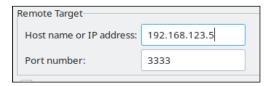

#### **Getting started**

- 2. Open the **Debug Configurations** window and select the **Debug (KitProg3\_MiniProg4)** configuration.
- 3. Do the following on the **Debugger** tab:
  - a. Copy the contents of the **Config options** text box and paste them to a text editor.
  - b. Replace all new lines with spaces because all configuration options should be in a single line separated by spaces.
  - c. Copy the contents to the clipboard. You will need to specify these options in the OpenOCD command line on a remote machine later.

- 4. Disable the **Start OpenOCD locally** checkbox.
- 5. Specify the **Host name or IP address** of the remote machine in the **Remote Target** group box.

6. Navigate to the **Startup** tab and make sure that the **Initial Reset** checkbox is checked and the **Reset Type** is set to **init**.

7. Click **Apply** to save changes to the launch configuration.

#### On a remote machine:

1. Type the following command in the command prompt, and then paste the configuration options from the clipboard to complete the command line (see <a href="step3">step 3</a> above).

```
openocd -c "bindto 0.0.0.0"
```

2. Replace the \${openocd\_path} with the full path to the OpenOCD executable on the remote machine.

The completed command line should look similar to the following:

```
rooi# openocd -c "bindto 0.0.0.0" -s "/root/.local/bin/../scripts" -s "./libs/TARGET_CY8CPROTO-062-4343W/COMPONENT_BSP
_DESIGN_MODUS/GeneratedSource" -c "source [find interface/kitprog3.cfg]" -c "puts stderr {Started by GNU MCU Eclipse}"
-c "source [find target/psoc6_2m.cfg]" -c "psoc6.cpu.cm4 configure -rtos auto -rtos-wipe-on-reset-halt 1" -c "gdb_por
t 3332" -c "psoc6 sflash_restrictions 1" -c "init; reset init"
```

- 3. Press [Enter] to start the OpenOCD session.
- 4. Switch back to a local machine and start the modified Debug (KitProg3\_MiniProg4) launch configuration.

## 3 Supported target configurations

Target configuration files are in the *target*/directory of the OpenOCD tree. To connect ModusToolbox<sup>™</sup> OpenOCD CLI to a device, pass one of the following configuration files as the argument for the <u>--file</u> command-line option; for example, -f target/psoc6.cfg.

#	Target config	Description
1	psoc6.cfg	CY8C6xx7, CY8C6xx6 target configuration
2	psoc6_2m.cfg	CY8C6xxA, CY8C6xx8 target configuration
3	psoc6_512k.cfg	CY8C6xx5 target configuration
4	psoc6_256k.cfg	CY8C6xx4 target configuration
5	psoc6_secure.cfg	CYB06447, CYB06447-BL target configuration
6	psoc6_2m_secure.cfg	CYS0644A, CYB0644A target configuration
7	psoc6_512k_secure.cfg	CYB06445 target configuration
8	psoc4.cfg	Configuration for all PSoC™ 4 MCU targets except PSoC™ 4500H MCU
9	psoc4500.cfg	Configuration file for PSoC™ 4500H MCU
10	cyw208xx.cfg	Configuration file for the AIROC™ CYW208xx Wi-Fi & Bluetooth® combo chips
11	bcm4390x.cfg <sup>2</sup>	Configuration file for CYW4390x family of devices

The CYW9WCD1EVAL1 kit is equipped with an onboard FTDI-based JTAG adapter. OpenOCD provides board-level configuration file for this kit which will configure the JTAG adapter and the CYW4390x chip automatically. Use single board/cyw9wcd1eval1.cfg configuration file for the CYW9WCD1EVAL1 board (instead of separate files for the probe and chip).

#### **Command-line options**

## 4 Command-line options

OpenOCD command-line options can be combined in a single command-line.

The most important options and commands:

Option	Description
file (-f)	Specifies the configuration file to use
search (-s)	Specifies the directory to search for configuration files
command (-c)	Executes an OpenOCD command. See OpenOCD Commands Overview for details.
debug (-d)	Specifies the debug level
log_output (-1)	Redirects the log output to the file
help (-h)	Displays the help message
version (-v)	Displays the OpenOCD version

## 4.1 --file (-f)

Specifies the configuration file to use.

Multiple configuration files can be specified from a command line. They are interpreted in the order they are specified in the command line.

```
openocd -f <filename.cfg>
openocd -f interface/ADAPTER.cfg -f target/TARGET.cfg
```

#### **Example:**

```
openocd -s ../scripts -f interface/jlink.cfg -c "transport select jtag" -f target/psoc6.cfg
```

The output should appear similar to the following:

The "tap/service found" message should appear with no warnings, which means the JTAG communication is working.

## OpenOCD CLI user guide

#### **Command-line options**

### 4.2 -- search (-s)

Specifies the directory to search for configuration files.

Multiple -s options can be specified. Configuration files and scripts are searched for in the following paths:

- the current directory
- any search directory specified on the command line using the -s option
- any search directory specified using the add script search dir command
- \$HOME/.openocd (not on Windows)
- a directory in the OPENOCD SCRIPTS environment variable (if set)
- the site-wide script library \$pkqdatadir/site
- the OpenOCD-supplied script library \$pkqdatadir/scripts.

The file first found with a matching file name is used.

```
openocd -s <directory>
```

#### **Example:**

```
openocd -s ../scripts -f interface/jlink.cfg -f target/psoc6.cfg
```

In this example, the -s option specifies the relative path to the directory where the interface and target configurations are located.

## 4.3 --command (-c)

Executes the Tcl command(s).

Multiple commands can be executed by either specifying the multiple -c options or passing several commands to the single -c options. In the latter case, separate the commands with a semicolon.

```
openocd -c <command>
openocd -c <"command1; command2; ...">
```

#### **Example:**

```
openocd -s ../scripts -f interface/jlink.cfg -f target/psoc6.cfg -c "targets; shutdown"
```

## 4.4 --debug (-d)

Specifies the debug level. The debug level is 2 by default.

```
openocd -d<n>
```

This affects the kind of messages sent to the server log:

- Level 0: Error messages only
- Level 1: Level 0 messages + warnings
- Level 2: Level 1 messages + informational messages
- Level 3: Level 2 messages + debugging messages

#### **Example:**

```
openocd -d1
```

## **OpenOCD CLI user guide**

### **Command-line options**

#### --log\_output (-l) 4.5

Redirects the log output to the file *logfile.txt*.

```
openocd -l <logfile.txt>
```

#### **Example:**

```
openocd -s ../scripts -f interface/jlink.cfg -f target/psoc6.cfg -l d:/log.txt -c
"targets; shutdown"
```

#### --help (-h) 4.6

Displays the help message.

```
openocd -h
```

#### --version (-v) 4.7

Displays the OpenOCD version.

```
openocd -v
```

#### **OpenOCD** commands overview

#### **OpenOCD commands overview** 5

The available OpenOCD Tcl commands are listed in the following table. You can combine several commands in a single command-line or pass them via the configuration file.

The command can be invoked with the -c command option.

Command	Description
version	Displays a string identifying the OpenOCD version
help	With no parameters, prints the help text for all commands
shutdown	Closes the OpenOCD server, disconnecting all clients
log output	Redirects logging to the filename; the initial log output channel is <i>stderr</i> .
debug_level	Displays the debug level
reset_config	Displays or modifies the reset configuration of your combination of the board and target
adapter speed	Sets the non-zero speed in kHz for the debug adapter
transport list	Displays the names of the transports supported by this version of OpenOCD
transport select	Selects a supported transport to use in this OpenOCD session
targets	Displays a table of all known targets, or sets the current target to a given target with a given name
scan_chain	Displays the TAPs in the scan chain configuration and their status
md(w)(h)(b)	Displays the contents of the address as 32-bit words (mdw), 16-bit half-words (mdh), or 8-bit bytes (mdb)
mw(w)(h)(b)	Writes the specified word (32 bits), half-word (16 bits), or byte (8-bit) value, at the specified address
init	Terminates the configuration stage and enters the run stage
reset [run] [halt] [init	Performs as hard a reset as possible, using SRST if possible
program	Programs a given programming file in the HEX, SREC, BIN, or ELF formats into flash
flash banks	Prints a one-line summary of each flash bank of the target device
flash list	Retrieves a list of associative arrays for each device that was declared using a flash bank numbered from zero
flash info	Prints info about the flash bank, a list of protection blocks, and their status
flash protect	Enables (on) or disables (off) protection of flash blocks
flash erase sector	Erases sectors in a given bank
flash erase address	Erases sectors starting at a given address
flash write bank	Writes the binary file to a given flash bank
flash write_image	Writes the image file to the current target's flash bank(s)
flash fill(w)(h)(b)	Fills the flash memory with the specified word (32 bits), half-word (16 bits), or byte
flash read_bank	Reads bytes from the flash bank and writes the contents to the binary file
flash verify_bank	Compares the contents of the binary file with the contents of the flash
flash padded value	Sets the default value used for padding-any-image sections
flash rmw	Can be used to modify flash individual bytes
add verify range	Allows specifying the memory regions to be compared during the <i>verify</i> operation

## **OpenOCD commands overview**

Command	Description
show_verify_ranges	Displays all active verify ranges for all targets that were added using the add_verify_range command. This command does not take any arguments.
clear_verify_ranges	Deletes all verify ranges for the specified target that were added using the add_verify_range command
verify_image	Verifies a file against the target memory starting at a given address
verify_image_checksum	Verifies a file against the target memory starting at a given address
<pre>load_image</pre>	Loads an image from a file to the target memory offset from its load address
<pre>dump_image</pre>	Dumps bytes of the target memory to a binary file
kitprog3 acquire_config	Controls device acquisition parameters, and optionally enables acquisition during the early initialization phase
kitprog3 acquire_psoc	Performs device acquisition
kitprog3 power_config	Controls KitProg3/MiniProg4 internal power supply parameters and optionally enables power
kitprog3 power_control	Turns on or off the KitProg3/MiniProg4 internal power supply
kitprog3 led_control	Controls KitProg3/MiniProg4 LEDs
kitprog3 get_power	Reports the target voltage in millivolts
psoc6 sflash restrictions	Enables or disables writes to SFlash regions other than USER, NAR, TOC2, and KEY
psoc6 allow efuse program	Allows or disallows writes to the EFuse region
psoc6 reset_halt	Simulates a broken vector catch on PSoC™ 6 MCUs
psoc6 secure_acquire	Enables or disables workarounds for the secure family of PSoC™ 6 MCUs
psoc4 reset halt	Performs alternate acquisition on PSoC™ 4 MCUs
psoc4 mass_erase	Performs a mass erase operation on the given flash bank
<pre>psoc4 chip_protect</pre>	Changes chip protection mode to PROTECTED
source	Reads a file and executes it as a Tcl script
find	Finds and returns the full path to a file with the Tcl script
set	Creates a Tcl variable
add script search dir	Adds a directory to the file/script search path
sleep	Waits for a given number of milliseconds before resuming

#### **OpenOCD commands description**

## 6 OpenOCD commands description

This section includes all relevant OpenOCD commands along with their descriptions and usage examples.

All examples described in this section can be executed against different PSoC<sup>™</sup> 6 or PSoC<sup>™</sup> 64 MCU targets. See <u>Supported Target Configurations</u> for the detailed list of available target devices and corresponding OpenOCD configuration files.

## 6.1 General OpenOCD commands

#### **6.1.1** version

Displays a string identifying the OpenOCD version.

#### **Example:**

```
openocd -c "version; shutdown"
```

#### 6.1.2 help

With no parameters, prints help text for all commands. Otherwise, prints each help-text-containing string. Not every command provides help text.

```
help [string]
```

#### **Example:**

```
openocd -c "help; shutdown"
```

#### 6.1.3 shutdown

Closes the OpenOCD server, disconnecting all clients (GDB, telnet, other). If the error option is used, OpenOCD will return non-zero exit code to the parent process.

```
shutdown [error]
```

#### **Example:**

```
openocd -c "shutdown error"
```

#### 6.1.4 log\_output

Redirects logging to the filename; the initial log output channel is stderr.

```
log output [filename]
```

#### **Example:**

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "log_output d:/log.txt; targets; shutdown"
```

### OpenOCD CLI user guide

#### **OpenOCD commands description**

### 6.1.5 debug\_level

Displays the debug level. If n (from 0..3) is provided, set it to that level.

This affects the kind of messages sent to the server log:

- Level 0: Error messages only
- Level 1: Level 0 messages + warnings
- Level 2: Level 1 messages + informational messages
- Level 3: Level 2 messages + debugging messages

The default is Level 2, but that can be overridden on the command line along with the location of that log file (which is normally the server's standard output).

```
debug level [n]
```

#### **Example:**

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "debug level 1; targets; shutdown"
```

#### 6.1.6 reset\_config

Displays or modifies the reset configuration of your combination of the board and target.

```
reset_config <mode_flag> ...
```

The mode\_flag options can be specified in any order, but only one of each type - signals, combination, gates, trst\_type, srst\_type and connect\_type - may be specified at a time. If you don't provide a new value for a given type, its previous value (perhaps the default) remains unchanged.

For example, do not say anything about TRST just to declare that if the JTAG adapter should want to drive SRST, it must explicitly be driven HIGH (srst push pull).

The signals option specifies which of the reset signals is/are connected.

For example, If the board doesn't connect SRST provided by the JTAG interface properly, OpenOCD cannot use it. The possible values are:

none (default)

```
trst_only
srst_only
trst and srst
```

See the OpenOCD documentation for details.

#### **Example:**

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "reset config trst and srst; targets; shutdown"
```

#### **OpenOCD commands description**

#### 6.1.7 adapter speed

Sets a non-zero speed in kHz for the debug adapter. Therefore, to specify 3 MHz, provide 3000.

```
adapter speed <max speed kHz>
```

JTAG interfaces usually support a limited number of speeds. The speed actually used will not be faster than the speed specified. Chip datasheets generally include a top JTAG clock rate. The actual rate is often a function of a CPU core clock, and is normally lower than that peak rate.

For example, most Arm® cores accept up to one sixth of the CPU clock. Speed 0 (kHz) selects the RTCK method. If your system uses RTCK, you will not need to change the JTAG clocking after a setup.

#### **Example:**

```
openocd -s ../scripts -f interface/jlink.cfg -c "transport select jtag; adapter speed 2000; shutdown"
```

## 6.1.8 transport list

Displays the names of the transports supported by this version of OpenOCD.

#### **Example:**

```
openocd -c "transport list; shutdown"
```

#### 6.1.9 transport select

Selects which of the supported transports to use in this OpenOCD session.

```
transport select < transport name>
```

When invoked with the transport\_name option, OpenOCD attempts to select the named transport. The transport must be supported by the debug adapter hardware and by the version of OpenOCD you are using (including the adapter's driver). If no transport has been selected and no transport\_name is provided, transport select auto-selects the first transport supported by the debug adapter. transport select always returns the name of the session's selected transport, if any.

#### **Example:**

```
openocd -s ../scripts -f interface/jlink.cfg -c "transport select jtag"
```

## **6.1.10** targets

With no parameter, this command displays a table of all known targets in a user-friendly form. With a parameter, this command sets the current target to a given target with a given *name*; this is relevant only to boards with more than one target.

```
targets [name]
```

#### **Examples:**

Displays all available targets of the connected PSoC™ 6 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "targets; shutdown"
```

## OpenOCD CLI user guide

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "targets psoc6.cpu.cm4; target current"
```

#### 6.1.11 scan\_chain

Displays the TAPs in the scan chain configuration, and their status. (Do not confuse this with the list displayed by the targets command. That only displays TAPs for CPUs configured as debugging targets.)

#### **Example:**

Displays TAPs of the PSoC<sup>™</sup> 6 MCU.

```
openocd -s ../scripts -f interface/jlink.cfg -c "transport select jtag; adapter speed 1000; init; scan chain; shutdown"
```

## $6.1.12 \quad md(w)(h)(b)$

Displays the contents of address addr, as 32-bit words (mdw), 16-bit half-words (mdh), or 8-bit bytes (mdb).

```
mdw [phys] <addr> [count]
mdh [phys] <addr> [count]
mdb [phys] <addr> [count]
```

When the current target has a present and active MMU, addr is interpreted as a virtual address. Otherwise, or if the optional phys flag is specified, addr is interpreted as a physical address. If count is specified, displays that many units.

#### **Example:**

Displays two 32-bit words of memory of the PSoC<sup>™</sup> 6 MCU.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; mdw 0x10000000 2; shutdown"
```

### OpenOCD CLI user guide

#### **OpenOCD commands description**

## 6.1.13 mw(w)(h)(b)

Writes the specified word (32 bits), halfword (16 bits), or byte (8-bit) value at the specified address addr.

```
mww [phys] <addr> <word>
mwh [phys] <addr> <halfword>
mwb [phys] <addr> <byte>
```

When the current target has a present and active MMU, addr is interpreted as a virtual address. Otherwise, or if the optional phys flag is specified, addr is interpreted as a physical address.

#### **Example:**

Write a 32-bit word to the memory of the PSoC<sup>™</sup> 6 MCU.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; mww 0x8000000 0xABCD1234; mdw 0x8000000; shutdown"
```

```

0x08000000: abcd1234
shutdown command invoked
```

#### 6.1.14 init

This command terminates the configuration stage and enters the run stage. This helps to have the startup scripts manage tasks such as resetting the target and programming flash. To reset the CPU upon a startup, add init and reset at the end of the config script or at the end of the OpenOCD command line using the -c command line switch.

If this command does not appear in any startup/configuration file, OpenOCD executes the command for you after processing all configuration files and/or command-line options.

Note:

This command normally occurs at or near the end of your config file to force OpenOCD to initialize and make the targets ready. For example: If your config file needs to read/write memory on your target, initialization must occur before the memory read/write commands.

#### Example (KitProg3 + PSoC™ 6 MCU target):

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; shutdown"
```

## 6.1.15 reset [run] [halt] [init]

Performs as hard a reset as possible, using SRST if possible. All defined targets will be reset, and target events will fire during the reset sequence.

The optional parameter specifies what should happen after a reset. If there is no parameter, a reset run is executed. The other options will not work on all systems. See <u>reset\_config</u>.

- run Let the target run
- halt Immediately halt the target
- init Immediately halt the target, and execute the reset-init script

# infineon

#### **OpenOCD commands description**

#### **Example:**

Reset and initialize the KitProg3 + PSoC<sup>™</sup> 6 MCU target:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init;
reset init; shutdown"\
```

## **6.1.16** program

Programs a given programming file in the HEX, SREC, ELF, or BIN formats into the flash of the target device.

```
program <filename> [preverify] [verify] [reset] [exit] [offset]
```

The only required parameter is filename; others are optional.

- preverify Performs the verification step before flash programming. Programming will be skipped if the flash contents match the data file.
- verify Compares the contents of the data file filename with the contents of the flash after flash programming
- reset "reset run" is called if this parameter is given (see reset for details)
- exit OpenOCD is shut down if this parameter is given.
- offset If relocation offset is specified, it is added to the base address for each section in the image.

#### **Example:**

The next example connects ModusToolbox™ OpenOCD CLI to the KitProg3 probe with the PSoC™ 6 MCU target, programs flash with the *firmware.hex* file, verifies programmed data, and finally shuts down the OpenOCD programmer.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "program d:/firmware.hex verify exit"
```

#### **OpenOCD commands description**

#### 6.1.17 flash banks

Prints a one-line summary of each flash bank of the target device.

#### Example (KitProg3 + PSoC™ 6 MCU):

openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; flash probe 0; flash probe 1; flash probe 2; flash probe 3; flash banks; shutdown"

#### 6.1.18 flash list

Retrieves a list of associative arrays for each device that was declared using a flash bank numbered from zero.

Example (KitProg3 + PSoC<sup>™</sup> 6 MCU):

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init;
reset init; flash list"
```

```
adapter_nsrst_delay: 200

{name psoc6 base 268435456 size 1048576 bus_width 0 chip_width 0 \ (name psoc6 base 335544320 size 0 bus_width 0 chip_width 0 \ (name psoc6 base 335544320 size 0 bus_width 0 chip_width 0 \ (name psoc6_efuse base 2423259136 size 1024 bus_width 1 chip_width 1 \ (name virtual base 268435456 size 1048576 bus_width 0 chip_width 0 \ (name virtual base 335544320 size 0 bus_width 0 chip_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752 size 0 bus_width 0 \ (name virtual base 369098752
```

## OpenOCD commands description

### **6.1.19** flash info

```
flash info <num> [sectors]
```

Prints info about the flash bank *num*, a list of protection blocks and their status. Uses sectors to show a list of sectors instead. The *num* parameter is a value shown by flash banks. This command will first query the hardware; it does not print cached and possibly stale information.

#### **Example:**

Prints the information about flash bank 0 of the KitProg3 + PSoC™ 6 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash info 0; shutdown"
```

```
#2042: 0x000ff400 (0x200 0kB) not protected
#2043: 0x000ff600 (0x200 0kB) not protected
#2044: 0x000ff800 (0x200 0kB) not protected
#2045: 0x000ff800 (0x200 0kB) not protected
#2046: 0x000ffc00 (0x200 0kB) not protected
#2046: 0x000ffc00 (0x200 0kB) not protected
#2047: 0x000ffc00 (0x200 0kB) not protected
Silicon ID: 0x2006fc00 (0x200 0kB) not protected
Protection: NORMAL
```

## 6.1.20 flash protect

Enables (on) or disables (off) protection of flash blocks in flash bank num, starting at protection block first and continuing up to and including last.

Note: This command is applicable for  $PSoC^{TM} 4 MCU$  only.

```
flash protect num first last (on|off)
```

Providing a last block of last specifies "to the end of the flash bank". The num parameter is a value shown by flash banks. The protection block is usually identical to a flash sector. Some devices may utilize a protection block distinct from the flash sector. See flash info for a list of protection blocks.

#### **Example:**

Protects all sectors from being written in flash bank 0 of the KitProg3 + PSoC™ 4 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc4.cfg -c "init; reset init; flash protect 0 0 last on; shutdown"
```

## OpenOCD CLI user guide

**OpenOCD commands description** 

#### 6.1.21 flash erase\_sector

Erases sectors in the bank num, starting at Sector first up to and including Sector last.

```
flash erase sector <num> <first> <last>
```

Sector numbering starts at 0. Providing the last sector of last specifies "to the end of the flash bank". The num parameter is a value shown by flash banks.

Note:

On  $PSoC^{m}4$  MCU devices, per-sector erase operation is not supported, only mass-erase is available. This command is ignored on  $PSoC^{m}4$  unless a full erase of the flash is requested (flash erase sector 0 0 last).

#### **Example:**

Erases all sectors in flash bank 0 of the KitProg3 + PSoC™ 6 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash erase sector 0 0 last; shutdown"
```

## 6.1.22 flash erase\_address

Erases the sectors starting at address for the length bytes.

```
flash erase address [pad] [unlock] <address> <length>
```

Unless pad is specified, address must begin a flash sector, and address + length - 1 must end a sector. Specifying pad erases the extra data at the beginning and/or end of the specified region, as needed to erase only full sectors. The flash bank to use is inferred from the address, and the specified length must stay within that bank. As a special case, when length is zero and address is the start of the bank, the whole flash is erased. If unlock is specified, the flash is unprotected before erase starts.

Note:

On  $PSoC^{m}4$  MCU devices, per-sector erase operation is not supported, only mass-erase is available. This command is ignored on  $PSoC^{m}4$  MCU unless a full erase of the flash is requested (e.g. flash erase address 0 65536 for 64 KB parts).

#### **Example:**

Erases the 2-KB block starting at address 0x10000000 of KitProg3 + PSoC™ 6 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash erase address 0x10000000 2048; shutdown"
```

## **OpenOCD commands description**

#### 6.1.23 flash write\_bank

Writes the binary filename to flash bank num, starting at offset bytes from the beginning of the bank.

```
flash write bank <num> <filename> <offset>
```

The num parameter is a value shown by flash banks.

#### **Example:**

Writes the binary file firmware.bin to flash bank 0 of KitProg3 + PSoC™ 6 MCU starting at offset 0:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash write bank 0 d:/firmware.bin 0x0; shutdown"
```

## 6.1.24 flash write\_image

Writes the image filename to the current target's flash bank(s).

```
flash write image [erase] [unlock] <filename> [offset] [type]
```

Only loadable sections from the image are written. If a relocation offset is specified, it is added to the base address for each section in the image. The file [type] can be specified explicitly as bin (binary), ihex (Intel hex), elf (ELF file), or s19 (Motorola s19). The relevant flash sectors will be erased prior to programming if the erase parameter is given. If unlock is provided, the flash banks are unlocked before erase and program. The flash bank to use is inferred from the address of each image section.

Attention: Be careful using the erase flag when the flash is holding data you want to preserve. Portions of the flash outside those described in the image's sections might be erased with no notice.

- When a section of the image being written does not fill out all the sectors it uses, the unwritten parts of those sectors are necessarily also erased, because sectors cannot be partially erased.
- Data stored in sector "holes" between image sections are also affected. For example, flash write\_image erase ... of an image with one byte at the beginning of a flash bank and one byte at the end erases the entire bank not just the two sectors being written.

Also, when flash protection is important, you must reapply it after it has been removed by the unlock flag.

#### **Example:**

Writes the ELF image *firmware.elf* to KitProg3 + PSoC<sup>™</sup> 6 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash write image erase d:/firmware.elf; shutdown"
```

## OpenOCD CLI user guide

#### **OpenOCD commands description**

## 6.1.25 flash fill(w)(h)(b)

Fills the flash memory with the specified word (32 bits), half-word (16 bits), or byte (8-bit) pattern, starting at address and continuing for length units (word/half-word/byte).

```
flash fillw <address> <word> <length>
flash fillh <address> <halfword> <length>
flash fillb <address> <byte> <length>
```

No erase is done before writing; when needed, that must be done before issuing this command. Writes are done in blocks of up to 1024 bytes, and each write is verified by reading back the data and comparing it to what was written. The flash bank to use is inferred from the address of each block, and the specified length must stay within that bank.

#### **Example:**

Fills the 32-KB block of the PSoC™ 6 MCU memory starting at address 0x10000000 with the pattern 0x5A:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash fillw 0x10000000 0x5A5A5A5A 0x2000; shutdown"
```

## 6.1.26 flash read\_bank

Reads the length bytes from the flash bank num starting at offset and writes the contents to the binary filename. The num parameter is a value shown by flash banks.

```
flash read bank <num> <filename> <offset> <length>
```

#### **Example:**

Reads the 32-KB block of bank #0 from the PSoC<sup>™</sup> 6 MCU memory and writes it to the binary file:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash read bank 0 d:/read bank 0.bin 0x0 0x8000; shutdown"
```

```

KiB/s)

shutdown command invoked
```

### OpenOCD CLI user guide

**OpenOCD commands description** 

## 6.1.27 flash verify\_bank

Compares the contents of the binary file filename with the contents of the flash num starting at offset. Fails if the contents do not match. The num parameter is a value shown by flash banks.

```
flash verify bank <num> <filename> <offset>
```

#### **Example:**

Verifies the content of bank #0 of the PSoC™ 6 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash verify bank 0 d:/firmware.bin 0x0; shutdown"
```

```

B/s)

contents match

shutdown command invoked
```

## 6.1.28 flash padded\_value

Sets the default value used for padding-any-image sections.

```
flash padded value <num> <value>
```

This should normally match the flash bank erased value. If not specified by this command or the flash driver, it defaults to 0xff.

#### **Example:**

Sets a padded value to 0xFF for bank #0 of the PSoC<sup>™</sup> 6 MCU.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash padded_value 0 0xFF; shutdown"
```

```
*** Device acquired successfully

Info: MainFlash size overridden: 1024 kB

Default padded value set to 0xff for flash bank 0

shutdown command invoked
```

#### **6.1.29** flash rmw

The command is intended to modify flash individual bytes.

```
flash rmw <address> <data>
```

The command can be used to program the data to an arbitrary flash address preserving all data that belongs to the same flash sector.

- address The start address for the programming.
- data The hexadecimal string with data to be programmed. The format of the string is shown in the following example:

Note:  $flash rmwis a custom command implemented in ModusToolbox^{\mathsf{TM}} OpenOCD CLI to extend its functionality.$ 

#### **OpenOCD commands description**

#### **Example:**

Modifies 8 bytes of the PSoC<sup>™</sup> 6 MCU flash at address 0x10001234.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; flash rmw 0x10001234 DEADBEEFBAADC0DE; shutdown"
```

## 6.1.30 add\_verify\_range

The command allows specifying memory regions to be compared during the verify operation.

```
add verify range <target> <address> <size>
```

By default, when no regions are defined, all the regions present in the firmware image file are compared with the corresponding target memory. This breaks the verification process for some non-memory-mapped regions such as EFuses. When the target has at least one <code>verify</code> region specified, only data that belongs to that <code>verify</code> region is verified.

- target The target device to assign verify regions.
- address The start address of the region.
- size The size of the region, in bytes.

Note:

The  $add\_verify\_range$  command is a custom command implemented in ModusToolbox<sup>TM</sup> OpenOCD CLI to extend its functionality.

## 6.1.31 show\_verify\_ranges

This command displays all active verify ranges for all targets that were added using the add\_verify\_range command. This command does not take any arguments.

#### **Example output:**

```
bin\openocd.exe -s scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init;
show verify ranges; exit"
```

Note:

The  $show\_verify\_ranges$  command is a custom command implemented in ModusToolbox<sup>™</sup> OpenOCD CLI to extend its functionality.

### OpenOCD CLI user guide

**OpenOCD commands description** 

## 6.1.32 clear\_verify\_ranges

This command deletes all verify ranges for the specified target that were added using the add\_verify\_range command.

```
clear verify ranges <target>
```

#### Example output:

bin\openocd.exe -s scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; clear verify ranges psoc6.cpu.cm4; show verify ranges; exit"

Note:

The  $clear\_verify\_ranges$  command is a custom command implemented in ModusToolbox<sup>M</sup> OpenOCD CLI to extend its functionality.

## 6.1.33 verify\_image

Verifies filename against the target memory starting at address. The file format may optionally be specified (bin, ihex, or elf). This will first attempt a comparison using a CRC checksum; if that fails, it will try a binary compare.

```
verify image <filename> <address> [bin|ihex|elf]
```

#### Examples:

Verifies a *firmware.elf* image against the target memory the PSoC<sup>™</sup> 6 MCU.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; verify image d:/firmware.elf 0x0; shutdown"
```

```
** SFlash SiliconID: 0xE2062200

** Flash Boot version: 0x021D8001

** Chip Protection: NORMAL

** psoc6.cpu.cm4: Ran after reset and before halt...

target halted due to debug-request, current mode: Thread

xPSR: 0x61000000 pc: 0x1600400c msp: 000000000

Info: MainFlash size overridden: 1024 kB

verified 72412 bytes in 0.275165s (256.991 KiB/s)

shutdown command invoked
```

## 6.1.34 verify\_image\_checksum

Verifies *filename* against the target memory starting at *address*. The file format may optionally be specified (bin, ihex, or elf). This perform a comparison using a CRC checksum only.

```
verify image checksum <filename> <address> [bin|ihex|elf]
```

#### **Example:**

Verifies a *firmware.elf* image against the target memory of the PSoC<sup>™</sup> 6 MCU using the CRC checksum only.

```
openocd -s ../scripts -f interface/jlink.cfg -c "transport select swd" -f target/psoc6.cfg -c "init; reset init; verify_image_checksum d:/firmware.elf 0x0; shutdown"
```

#### **OpenOCD commands description**

## 6.1.35 load\_image

Loads an image from file filename to the target memory offset by address from its load address. The file format may optionally be specified (bin, ihex, elf, or s19). Also, the following arguments may be specified:

- min addr Ignore the data below min\_addr (this is w.r.t. to the target's load address + address)
- max\_length Maximum number of bytes to load load image filename address [[bin|ihex|elf|s19] min addr max length]

#### **Examples:**

Loads the binary file *firmware.bin* to the RAM of the PSoC<sup>™</sup> 6 MCU.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; load image d:/firmware.bin 0x8000000; shutdown"
```

```
** SFlash SiliconID: 0xE30021FF

xPSR: 0x01000000 pc: 0x0000010c msp: 0x0801f800

32768 bytes written at address 0x08000000

downloaded 32768 bytes in 0.640384s (49.970 KiB/s)

shutdown command invoked
```

## 6.1.36 dump\_image

Dumps size bytes of the target memory starting at address to the binary file named filename.

```
dump image <filename> <address> size
```

#### Example:

Dumps 8 KB of the PSoC<sup>™</sup> 6 MCU memory to the file *dump\_mem.bin*.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; dump_image d:/dump_mem.bin 0x10001234 0x2000; shutdown"
```

## ModusToolbox<sup>™</sup> software

### OpenOCD CLI user guide

#### **OpenOCD commands description**

## 6.2 KitProg3/MiniProg4 driver commands

The KitProg3/MiniProg4 probe implements the CMSIS-DAP protocol defined by Arm® with some extensions. Consequently, the KitProg3/MiniProg4 driver in OpenOCD is a wrapper around the native CMSIS-DAP driver that extends its functionality with the KitProg3-specific extensions.

A full list of the CMSIS-DAP-specific configuration commands can be found in the OpenOCD official documentation.

Besides the standard CMSIS-DAP options, the KitProg3 driver exposes several custom Tcl configuration commands. All commands in this section must be prefixed with the name of the driver – "kitprog3".

## 6.2.1 kitprog3 acquire\_config

The command controls device acquisition parameters and optionally enables acquisition during the early initialization phase. Can be called at any time.

```
acquire config <status> [target type] [mode] [attempts] [timeout] [ap]
```

- status A mandatory parameter, enables or disables the acquisition procedure during the initialization phase. The possible values: On, Off.
- target\_type Specifies the target device type. This parameter is mandatory only if status=on. The possible values:
  - 0 PSoC4
  - 1 PSoC5
  - 2 PSoC6
- mode Specifies the acquisition mode. This parameter is mandatory only if status=on. The possible values: 0 Reset, 1 Power Cycle. The mode affects only the first step(how to reset the part at the start of the acquisition flow).
  - Reset mode: To start programming, the host toggles the XRES line and then sends SWD/JTAG commands
  - Power Cycle mode: To start programming, the KitProg3-based probe powers on the MCU and then starts sending the SWD/JTAG commands. The XRES line is not used. Power Cycle mode support is optional and should be used only if the XRES pin is not available on the part's package.

Note: Before using Power Cycle acquisition, make sure that the target is not powered externally!

- attempts The number of attempts to acquire the target device. This parameter is mandatory only if status=on.
- timeout (Optional) Timeout value in seconds. The maximum value for the timeout is 30 seconds.
- ap Access port to use for the acquisition. The value of this parameter should be in range 0...255. This parameter is mandatory if the timeout parameter is specified.

#### **Example:**

openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "kitprog3 acquire\_config on 2 0; init; reset init; shutdown"

## OpenOCD commands description

## 6.2.2 kitprog3 acquire\_psoc

Performs device acquisition. Called only after the initialization phase. The acquisition procedure must be configured using acquire\_config before calling this command.

#### Example:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "kitprog3 acquire config on 2 0; init; kitprog3 acquire psoc; reset init; shutdown"
```

## 6.2.3 kitprog3 power\_config

Controls the KitProg3-internal power supply parameters and optionally enables power during the early initialization phase. Can be called at any time.

```
kitprog3 power config <status> [voltage]
```

- status Mandatory; enables or disables power supply during the initialization phase. Possible values: on | off.
- voltage The power supply voltage in millivolts. Mandatory only if status=on.

#### **Example:**

openocd -s ../scripts -f interface/kitprog3.cfg -c "kitprog3 power\_config on 3300; init; shutdown"

```

shutdown command invoked
```

## 6.2.4 kitprog3 power\_control

The command turns on or off the KitProg3 internal power supply. Can be called only after the initialization phase.

```
kitprog3 power control <status>
```

The voltage must be configured using power config before calling this command.

status - Mandatory; enables or disables power supply: on | off.

# Infineon

#### **OpenOCD commands description**

#### **Example:**

openocd -s ../scripts -f interface/kitprog3.cfg -c "kitprog3 power\_config on 3300; init; kitprog3 power control off; shutdown"

## 6.2.5 kitprog3 led\_control

Controls the KitProg3 LEDs. Can be called only after the initialization phase.

```
kitprog3 led control <type>
```

- type Mandatory; specifies the type of the LED indication. The possible values:
  - 0 Ready
  - 1 Programming
  - 2 Success
  - 3 Error

#### **Example:**

```
openocd -s ../scripts -f interface/kitprog3.cfg -c "init; kitprog3 led control 2"
```

## 6.2.6 kitprog3 get\_power

Reports the target voltage in millivolts. Can be called only after the initialization phase.

#### **Example:**

```
openocd -s ../scripts -f interface/kitprog3.cfg -c "init; kitprog3 get_power;
shutdown"
```

## 6.2.7 cmsis\_dap\_serial

Specifies the serial number of the KitProg3/MiniProg4 device to use. If not specified, serial numbers are not considered. Command can be used to specify which device to use if multiple devices are connected to the host PC.

### OpenOCD CLI user guide

**OpenOCD commands description** 

#### 6.3 Flash driver commands

This section contains flash driver commands for PSoC<sup>™</sup> 6 MCUs.

#### 6.3.1 psoc6 sflash\_restrictions

The command enables or disables writes to SFlash regions other than USER, NAR, TOC2, and KEY.

```
psoc6 sflash restrictions <mode>
```

The command can be called at any time. Writes to these regions are possible only on the VIRGIN silicon, so the command is mostly intended for internal use. It is useful for flash boot developers and validation teams. Note that *erase* (performed by programming with zeros for PSoC<sup>™</sup> 6 MCU) is performed only for the USER, NAR, TOC2, and KEY regions; it is skipped for other SFlash regions regardless of this command.

- mode Mandatory; specifies the behavior of SFlash programming. The possible values:
  - 0 Erase/Program of SFlash is prohibited.
  - 1 Erase and Program of USER/TOC/KEY is allowed.
  - 2 Erase of USER/TOC/KEY and program of USER/TOC/KEY/NAR is allowed.
     Be aware that the NAR sub-region cannot be overwritten or erased if the new data is less restrictive than the existing data. Unintentional writing to this region may corrupt your device!
  - 3 Erase of USER/TOC/KEY and program of the whole SFlash region is allowed.

#### Example (KitProg3 + PSoC™ 6 MCU):

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; psoc6 sflash restrictions 2; shutdown"
```

```
** SFlash SiliconID: 0xE2062200

** Flash Boot version: 0x021D8001

** Chip Protection: NORMAL

** psoc6.cpu.cm4: Ran after reset and before halt...

target halted due to debug-request, current mode: Thread

xPSR: 0x61000000 pc: 0x1600400c msp: 00000000

Warn : SFlash programming allowed for regions: USER, TOC, KEY, NAR

shutdown command invoked
```

## 6.3.2 psoc6 allow\_efuse\_program

Allows or disallows writes to the EFuse region. Can be called any time. Writes to the EFuse region are skipped by default. Be aware that EFuses are one-time programmable. Once an EFuse is blown, there is no way to revert its state. EFuse programming must be allowed for lifecycle transitions to work.

```
psoc6 allow efuse program <on|off>
```

#### **Example:**

Writes 1 bit to the EFuse region at address 0x907003FF of the PSoC<sup>™</sup> 6 MCU:

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; psoc6 allow_efuse_program on; flash fillb 0x907003FF 1 1; flash read bank 3 d:/dump efuse.bin 0x3FF 0x1; shutdown"
```

```
Warn: Programming of efuses now ALLOWED
Info: MainFlash size overridden: 1024 kB
Info: Start address 0x907003ff breaks the required alignment of flash bank psoc6_efuse_cm0
Info: Padding 1023 bytes from 0x90700000
Info: The Life Cycle stage is not present in the programming file
wrote 1 bytes to 0x907003ff in 0.062402s (0.016 KiB/s)
wrote 1 bytes to file d:/dump_efuse.bin from flash bank 3 at offset 0x000003ff in 0.015601s (0.063 KiB/s)
shutdown command invoked
```

## ModusToolbox<sup>™</sup> software

#### OpenOCD CLI user guide

#### **OpenOCD commands description**

#### 6.3.3 psoc6 reset\_halt

The command simulates a broken vector catch on PSoC<sup>™</sup> 6 MCUs.

```
psoc6 reset halt <mode>
```

The command retrieves the address of the vector table from the VECTOR\_TABLE\_BASE registers, detects the location of the application entry points, sets a hardware breakpoint at that location, and performs a reset of the target. The type of the reset can be specified by the optional mode parameter.

#### **Parameters:**

• mode – (Optional) The type of reset to be performed. Possible values are sysresetreq and vectreset. If not specified, SYSRESETREQ is used for the CMO core and VECTRESET is used for other cores in the system.

#### Example (KitProg3 + PSoC™ 6 MCU):

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc6.cfg -c "init; reset init; psoc6 reset halt vectreset; shutdown"
```

```
** SFlash SiliconID: 0xE2062200

** Flash Boot version: 0x02108001

** Chip Protection: NORMAL

** protection: NORMAL

** protection: NoRMAL

target halted due to debug-request, current mode: Thread

xPSR: 0x61000000 pc: 0x1600400c msp: 00000000

Info: protection: bkpt 00x100014B9, issuing VECTRESET

shutdown command invoked
```

## 6.3.4 psoc6 secure\_acquire

Performs acquisition of PSoC<sup>™</sup> 64 "Secure Boot" MCUs.

```
psoc6 secure_acquire <magic_num_addr> <mode> <handshake> <timeout>
```

#### **Parameters:**

- magic\_num\_addr Address in RAM to poll for the magic number. This address is different across different
   PSoC™ 6 MCU devices:
  - CYB06447, CYB06447-BL 0x08044804
  - CYS0644A, CYB0644A 0x080FE004
  - CYB06445 0x0803E004
- mode -Mode of acquisition. Possible values: run, halt.
  - In run mode, the command will perform reset and will wait for the "secure" application to open the corresponding access port.
  - In halt mode, a "secure" handshake will be performed right after reset to prepare the device for flash programming.
- handshake Specifies whether full or short acquisition procedure should be executed. The short acquisition procedure simply waits until "secure" FW opens the given access port. This is intended for multi-core configuration when full acquisition has already been done with the other CPU core.
  - Possible values: handshake full acquisition, no handshake short acquisition
- timeout -Timeout in milliseconds

## ModusToolbox™ software

## OpenOCD CLI user guide OpenOCD commands description

## 6.3.5 psoc4 reset halt

Performs the alternate acquire sequence as described in the PSoC<sup>™</sup> 4 MCU programming specification.

```
psoc4 reset halt
```

The command detects the location of the application entry points, sets a hardware breakpoint at that location, and issues a SYSRESETREQ reset.

#### Example (KitProg3 + PSoC™ 4 MCU):

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc4.cfg -c "init; reset init; psoc4 reset halt; shutdown"
```

## 6.3.6 psoc4 mass\_erase

Performs mass erase operation on the given flash bank. The list of all flash banks can be obtained using flash banks command. This command is a shortcut and performs the same operation as the flash erase\_sector <br/>
<br/>
<br/>
| bank\_id> 0 last command. The peculiarity of this command is that erasing of the mflash bank also erases the flashp bank. If the chip is in PROTECTED state, this command moves the protection state of the device from PROTECTED to OPEN and erases the entire flash device. To move the chip from PROTECTED to OPEN state successfully, set the <a href="PSOC4">PSOC4 USE MEM AP variable</a>.

```
psoc4 mass erase <bank id>
```

#### Example (KitProg3 + PSoC™ 4 MCU):

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc4.cfg -c "init; reset init; psoc4 mass erase 0; shutdown"
```

## 6.3.7 psoc4 chip\_protect

Changes the chip protection mode to PROTECTED. This mode disables all debug access to the user code or memory. Access to most registers is still available; debug access to registers to reprogram flash is not available. Protection mode can be changed back to OPEN by performing the mass erase operation described above.

```
psoc4 chip_protect
```

### Example (KitProg3 + PSoC™ 4 MCU):

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/psoc4.cfg -c "init; reset init; psoc4 chip protect; shutdown"
```

## ModusToolbox<sup>™</sup> software

## OpenOCD CLI user guide

#### **OpenOCD commands description**

## 6.4 cmsis\_flash flash driver commands

The "cmsis\_flash" is a generic driver which uses the standard CMSIS flash loaders to program the flash. On Infineon devices, this driver is typically used for external flash programming but it also can be used for other purposes.

## 6.4.1 cmsis\_flash init

Some types of flash banks are not mapped to the CPU address space right after reset. For example, the external flash connected to an SMIF peripheral requires special configuration of the MCU's hardware blocks in order to be mapped to the CPU address space. Usually, the flash loader's Init() function is responsible for enabling such mapping.

```
cmsis flash init [bank num]
```

This command loads the flash loader to the RAM and executes the <code>Init()</code> function. Beware that this function is intrusive. It requires that the MCU is acquired in "good-state" and all CPUs are halted (e.g., <code>reset init</code> is performed) before it can be called.

This command takes one optional argument – the number of the flash bank to be initialized. This command will initialize all cmsis flash banks if no argument is specified.

## 6.4.2 cmsis\_flash prefer\_sector\_erase

Controls driver strategy used during mass-erase of the flash bank. There are two possible strategies:

- Use the EraseChip API (if available)
- Use per-sector erase using the EraseSector API

The EraseChip method is used by default. This method is usually faster but it does not display the progress of the erase operation. The EraseChip API is optional; the driver will fall back to per-sector erase if the EraseChip API is not implemented in the flash loader. The other downside of this method is that depending on the flash loader implementation, it may erase all external memory banks, not only the bank specified in the erase sector command.

Per-sector erase is usually slower but it displays the progress information and always erases the single flash bank specified in the erase sector command.

```
cmsis_flash prefer_sector_erase [bank_num] <0/1|false/true>
```

Command takes two arguments:

- bank\_num (Optional) Flash bank number to enable/disable the per-sector erase strategy. This option will be applied to all cmsis\_flash banks if this argument is omitted.
- parameter\_value Mandatory boolean value specifying whether per-sector strategy should be enabled or disabled.

## ModusToolbox™ software

## OpenOCD CLI user guide

#### **OpenOCD commands description**

### 6.5 Other commands

#### **6.5.1** source

Reads a file and executes it as a script. It is usually used with the result of the find command.

```
source [find FILENAME]
```

#### Example (KitProg3 + PSoC™ 6 MCU):

```
openocd -s ../scripts -c "source [find interface/kitprog3.cfg]; source [find target/psoc6.cfg]; targets; shutdown"
```

#### 6.5.2 find

Finds and returns a full path to a file with a given name. It is usually used as an argument of the source command. This command uses an internal search path. (Do not try to use a filename which includes the "#" character. That character begins Tcl comments.)

```
source [find FILENAME]
```

#### **Example:**

```
openocd -s ../scripts -c "source [find interface/kitprog3.cfg]; source [find target/psoc6.cfg]; targets; shutdown"
```

#### 6.5.3 set

Stores a value to a named variable, first creating the variable if it does not already exist.

```
set VARNAME value
```

#### **Example:**

```
openocd -s ../scripts -c "set ENABLE_CM0 0; source [find interface/kitprog3.cfg];
source [find target/psoc6.cfg]; targets; shutdown"
```

## 6.5.4 sleep

Waits for at least msec milliseconds before resuming. Useful in a combination with script files.

```
sleep msec
```

#### **Example:**

```
openocd -c "sleep 1000; shutdown"
```

## 6.5.5 add\_script\_search\_dir

Adds a directory to a file/script search path. Equivalent to the --search command-line option.

```
add script search dir [directory]
```

#### **Example:**

```
openocd -c "add_script_search_dir ../scripts; source [find
interface/kitprog3.cfg]; source [find target/psoc6.cfg]; targets; shutdown"
```

## ModusToolbox<sup>™</sup> software

## OpenOCD CLI user guide

**OpenOCD commands description** 

### 6.6 CYW4390x commands

The CYW4390x chip supports only limited subset of flash-related commands. Currently, the following flash programming commands are supported:

## 6.6.1 program

Programs a given binary programming into the flash of the target device.

```
program <filename> [reset] [exit]
```

The only required parameter is filename; the others are optional.

- reset Calls reset run (see reset for details)
- exit Shuts down OpenOCD

Limitations compared to standard program command:

- Only binary files are supported. Files in any format other than binary will be programmed as a binary data. For example, if a HEX file is programmed, the flash will contain textual representation of the file.
- The preverify, verify, and offset parameters are not supported. Verification is done automatically during programming.

#### **Example:**

The next example connects ModusToolbox™ OpenOCD CLI to the CYW9WCD1EVAL1 board with the CYW4390x MCU target, programs the flash with the *firmware.bin* file, resets the target, and finally shuts down the OpenOCD programmer.

```
openocd -s ../scripts -f board/cyw9wcdleval1.cfg -c "program d:/firmware.bin reset exit"
```

## 6.6.2 erase\_all

Erases the external flash memory chip.

#### **Example:**

```
openocd -s ../scripts -f board/cyw9wcdleval1.cfg -c "erase all; exit"
```

### **OpenOCD commands description**

## 6.7 AIROC™ CYW20829 Wi-Fi & Bluetooth® combo chip commands

## 6.7.1 provision\_no\_secure

Performs a transition from NORMAL to NORMAL\_NO\_SECURE lifecycle. CYW20829 devices come from a factory in the NORMAL lifecycle stage. In this stage, the boot code will not launch the programmed application after reset. The lifecycle must be changed to either SECURE or NORMAL\_NO\_SECURE stage to use the device. Normally, this task is performed using *cysecuretools*; this command is just a shortcut which simplifies the process. Transition to the SECURE lifecycle is not supported by this command and must be performed using *cysecuretools*.

Note: This command must be executed before the init command.

```
provision_no_secure <service_app> <app_params> [service_app_addr] [params_addr]
```

### **Required parameters:**

- service app File name of the binary service application image, with path
- app params File name of the service application's parameters image, with path

#### **Optional parameters:**

service\_app\_addr - Address in the RAM where the service application will be loaded; 0x20004000 by default.

params\_addr - Address in the RAM where the service application's parameters will be loaded; 0x2000D000 by default.

## **Example:**

The next example connects ModusToolbox™ OpenOCD CLI to the CYW9WCD1EVAL1 board with the CYW4390x MCU target, programs the flash with the *firmware.bin* file, resets the target, and finally shuts down the OpenOCD programmer.

```
openocd -s ../scripts -f interface/kitprog3.cfg -f target/cyw20829.cfg -c "provision no secure D:/service app.bin D:/app params.bin; exit"
```

## ModusToolbox™ software OpenOCD CLI user guide

#### **Global variables**

## 7 Global variables

The global variables listed in this section control the behavior of a target configuration file (e.g., *psoc6.cfg*). They are set in the command-line before any configuration file such as *kitprog3.cfg* or *psoc6.cfg*. See the command <u>set</u> for details.

## 7.1 PSoC™ 6 MCU global variables

## 7.1.1 ENABLE\_ACQUIRE

Enables or disables the acquisition of the target device in test mode.

#### Possible values:

- 1 Reset acquisition enabled (default with KitProg3/MiniProg4)
- 2 <u>Power Cycle</u> acquisition enabled. The voltage level can be controlled by using <u>ENABLE POWER SUPPLY.</u>
- 0 Acquisition disabled (default for other debug adapters)

## 7.1.2 ENABLE\_POWER\_SUPPLY

Controls the internal power supply of KitProg3/MiniProg4 adapters. If this command is specified, the KitProg3 driver enables the power supply, thus powering on the target during initialization.

#### Possible values:

- 0 Power supply disabled
- Any other value defines target voltage in millivolts.
- default Sets the last used voltage before KitProg3/MiniProg4 was powered off.

## 7.1.3 ENABLE\_CMO, ENABLE\_CM4

Allows specifying the CPU cores to be visible to OpenOCD. OpenOCD never affects disabled cores.

#### Possible values:

- 1 Corresponding core is enabled.
- 0 Core is disabled.

#### 7.1.4 TARGET AP

Applicable for "secure" (PSoC™ 64) MCUs only. Enables the choice of DAP access port that will be used for programming.

#### Possible values:

- sys\_ap SYS\_AP (AP #0, default)
- cm0\_ap CM0\_AP (AP #1)
- cm4\_ap CM4\_AP (AP #2). Choosing this access port will enable external SMIF memory banks.

# ModusToolbox™ software OpenOCD CLI user guide

#### **Global variables**

## 7.1.5 FLASH\_RESTRICTION\_SIZE

Applicable for "secure" (PSoC<sup>™</sup> 64) MCUs only. Use this variable to limit the size of accessible flash so OpenOCD will not affect flash locations where the "secure" CyBootloader is located. The default value of this variable varies across different PSoC<sup>™</sup> 64 MCUs.

## 7.1.6 ENABLE\_WFLASH, ENABLE\_SFLASH, ENABLE\_EFUSE

Applicable for "secure" (PSoC 64) MCUs only. Enables the corresponding flash bank when set to a non-zero value. The WorkFlash is enabled by default on PSoC™ 64 CYS0644A, CYB0644A, CYB06447 and CYB06447-BL MCU devices. SFlash and eFuse banks are disabled by default on all PSoC™ 64 MCU targets.

## 7.1.7 SMIF\_BANKS

Defines QSPI memory banks. This variable is a two-dimensional associative Tcl array of the following format:

```
set SMIF_BANKS {
   1 {addr <XIPaddr1> size <BankSz1> psize <ProgramSz1> esize <EraseSz1>}
   2 {addr <XIPaddr2> size <BankSz2> psize <ProgramSz2> esize <EraseSz2>}
   ...
   N {addr <XIPaddrN> size <BankSzN> psize <ProgramSzN> esize <EraseSzN>}
}
```

#### Where:

- XIPaddrN XIP mapping address
- BankSzN Total size of this flash bank, in bytes
- ProgramSzN Minimal programming granularity (program block size), in bytes
- EraseSzN Minimal erase granularity (erase block size), in bytes

## 7.2 PSoC™ 4 MCU global variables

## 7.2.1 PSOC4\_USE\_ACQUIRE

Enables or disables the acquisition of the target device in test mode.

#### Possible values:

- 1 Reset acquisition enabled (default with KitProg3/MiniProg4)
- 2 <u>Power Cycle</u> acquisition enabled. The voltage level can be controlled by using <u>ENABLE POWER SUPPLY</u>.
- 0 Acquisition disabled (default for other debug adapters)

## 7.2.2 PSOC4\_USE\_MEM\_AP

Enables creating a mem\_ap target instead of the default cortex\_m. Intended to be used to move chip protection state from PROTECTED to OPEN via the mass\_erase command.

#### **Possible values:**

- 1 mem ap target creation enabled. Only basic memory read/write works with this option.
- 0 cortex m target creation enabled (default)

## **Global variables**

#### AIROC™ CYW20829 Wi-Fi & Bluetooth® combo chip global variables 7.3

#### 7.3.1 **DEBUG\_CERTIFICATE**

Allows to specify the location of the debug certificate binary file. This variable is used to configure a secure debug session. OpenOCD checks the status of the CM33 access port during the initialization phase and after each reset. It will attempt to reopen the CM33 AP by sending a debug certificate to a target and issuing WFA request #2.

This variable should contain the full path to the debug certificate binary file.

#### 7.3.2 **DEBUG\_CERTIFICATE\_ADDR**

(Optional) Allows to specify the location in the RAM where the debug certificate will be loaded. The default address 0x2000FC00 will be used if this variable is not set by the user.

#### 7.3.3 **SMIF\_BANKS**

See <u>SMIF\_BANKS section</u> under PSoC 6<sup>™</sup> MCU.

**Usage examples** 

#### **Usage examples** 8

All the examples in this chapter assume that you have a PSoC<sup>™</sup> 6 MCU target connected to the PC via the KitProg3/MiniProg4 or J-Link debug probe. The current working directory is the default install directory (for example, c:\Program Files (x86)\Cypress\Cypress Programmer\openocd\bin on Windows).

For convenience, the psoc6\_kp3\_board.cfg config file has been created in the same directory as the OpenOCD executable. The file contains the default configuration suitable for the majority of PSoC™ 6 MCU kits:

```
source [ find interface/kitprog3.cfg ]
source [ find target/psoc6.cfg ]
init
reset init
```

See Supported target configurations for a detailed list of available target devices and corresponding OpenOCD configuration files.

#### Erase main flash rows 0...10 of PSoC™ 6 MCU 8.1

```
openocd -s ../scripts -f psoc6 kp3 board.cfg -c "flash erase sector 0 0 10; exit"
```

**Usage examples** 

## 8.2 Display memory contents (32 words at address 0x08000000) of PSoC™ 6

openocd -s ../scripts -f psoc6 kp3 board.cfg -c "mdw 0x08000000 32; exit"

```
A possible output of OpenOCD:

Upen Un-Chip Bebugger 0:10:00+dev-2:1:0.b5 (2018-12-27-05:43)
Licensed under GNU GPL v2
For bug reports, read lorg/doc/doxygen/bugs.html
adapter speed: 1000 kHz
adapter speed: 1000 kHz
** Auto-acquire enabled, use "set ENABLE_ACQUIRE O" to disable
cortex_m reset_config vscresetreq
```

**Usage examples** 

#### Program the PSoC™ 6 MCU with verification (Intel HEX file) 8.3

OpenOCD supports programming of the ELF, Intel HEX, Motorola SREC, and binary file formats. For binary files, the relocation offset must be specified as an argument to the program command.

```
openocd -s ../scripts -f psoc6 kp3 board.cfg -c "program d:/BlinkyLED.hex verify
reset; exit"
```

```
Apossible Output to Opter to 18.0*dev-2.1.0.65 (2018-12-27-05:43)

Licensed under CMU GPL v2

Licensed
```

**Usage examples** 

#### Program the EFuse region of PSoC™ 6 MCU 8.4

This example writes a single bit of data to the EFuse region of the PSoC™ 6 MCU at address 0x907003FE:

openocd -s ../scripts -f interface/kitproq3.cfg -f target/psoc6.cfg -c "init; reset init; psoc6 allow efuse program on; flash fillb 0x907003FE 1 1; flash read bank 3 d:/dump efuse.bin 0x3FE 0x1; exit"

```
A possible output of OpenOCD:

Open On-Chip Debugger 0.10.0+dev-2.1.0.72 (2019-01-12-12:22)
Licensed under GNU GPL v2
For bug reports, read
Attp://openocd.org/doc/doxygen/bugs.html
adayter profits profits for the disable cortex_n prest_config verterest

**Usage examples** 

#### Modify individual bytes of PSoC™ 6 MCU in main flash and display 8.5 results

openocd -s ../scripts -f psoc6 kp3 board.cfg -c "mdw 0x10000000 8; flash rmw 0x10000002 11223344; mdw 0x10000000 8; exit"

**Usage examples** 

#### Read the memory of PSoC™ 6 MCU to binary file 8.6

The example reads 32 KB of the PSoC™ 6 MCU memory to a file named dump\_mem.bin.

```
openocd -s ../scripts -f interface/kitproq3.cfg -f target/psoc6.cfg -c "init;
reset init; dump image d:/dump mem.bin 0x10000000 0x8000; exit"
```

A possible output of OpenOCD:

```
Open On-Chip Debugger 0.10.0+dev-2.1.0.72 (2019-01-12-12:22)
Licensed under GNU GPL v2
For bug reports, read
      reports, read

```

#### 8.7 Start the GDB server and leave it running

```
openocd -s ../scripts -f psoc6 kp3 board.cfg
```

## **ModusToolbox™ software** OpenOCD CLI user guide

## **Revision history**

## **Revision history**

Revision	Date	Description
**	1/17/19	New document.
*A	01/24/19	Updated installation procedures for Windows and Linux sections.
*B	04/16/19	Updated for version 2.2. Added CY8C6xx5 configuration.
		Added descriptions for show_verify_ranges, clear_verify_ranges, and psoc6 secure_app commands.
*C	06/26/19	Removed all Traveo II (automotive) related information
*D	12/13/19	Changed document name from CYPRESS™ Programmer 2.2 OpenOCD CLI User Guide to Cypress OpenOCD CLI User Guide.
		Clean-up in whole document.
		Deleted section 2 – Cypress Programmer Installation.
		Updated Supported Target Configurations table.
		Added description for "TARGET_AP" and "FLASH_RESTRICTION_SIZE" variables.
		Added "psoc6 secure_acquire" and deleted "psoc6 secure_app" commands.
		Added "cmsis_dap_serial" command description.
*E	03/16/20	Added PSoC 4-related descriptions.
*F	03/19/20	Added "flash protect" command description.
		Added description of ENABLE_WFLASH, ENABLE_SFLASH, ENABLE_EFUSE variables.
*G	6/11/2020	Added mention of the latest released version of Cypress OpenOCD is located
		on GitHub: <a href="https://github.com/cypresssemiconductorco/openocd/releases">https://github.com/cypresssemiconductorco/openocd/releases</a>
		Updated section "Supported MCU Devices"
		Updated section "Supported Target Configurations"
		Updated description of "kitprog3 acquire_config" and "psoc6 secure_acquire" commands
*H	7/29/2020	Added configuration file for CY8C6xx4 device
*I	2/8/2020	Added description for "psoc4 chip_protect" command
		Added configuration file for PSoC 4500H
		Updated "flash erase_sector" and "flash erase_address" sections – document limitations of PSoC4 chips
		Updated "PSOC4_USE_ACQUIRE", "ENABLE_ACQUIRE", "kitprog3 acquire_config" sections – add support for power-cycle acquisition mode
*J	09/10/2021	Updated document title to ModusToolbox™ software OpenOCD CLI user guide
	, ,	Added description for the cmsis_flash driver and related commands
		Added description for global variables used with CYW20829 target
		Added CYW20829-specific commands
		Added CYW4390x-specific commands and limitations
		Added example of remote PSoC6 debugging configuration
